

## Victims' Report

Six people were chosen for the experiment. Each of six people passed away either by homicide or suicide. Weather Underground is used to get temperature and humidity. VPD is calculated as follows:

$$\text{VPD} = 610.78 \cdot \exp\left(\frac{T}{T + 237.3}\right) \times 17.2694 \cdot (1 - \text{RH}/100) = \text{VPD}$$

where T is the temperature in Celcius and RH is relative humidity. Excel is used for calculations.

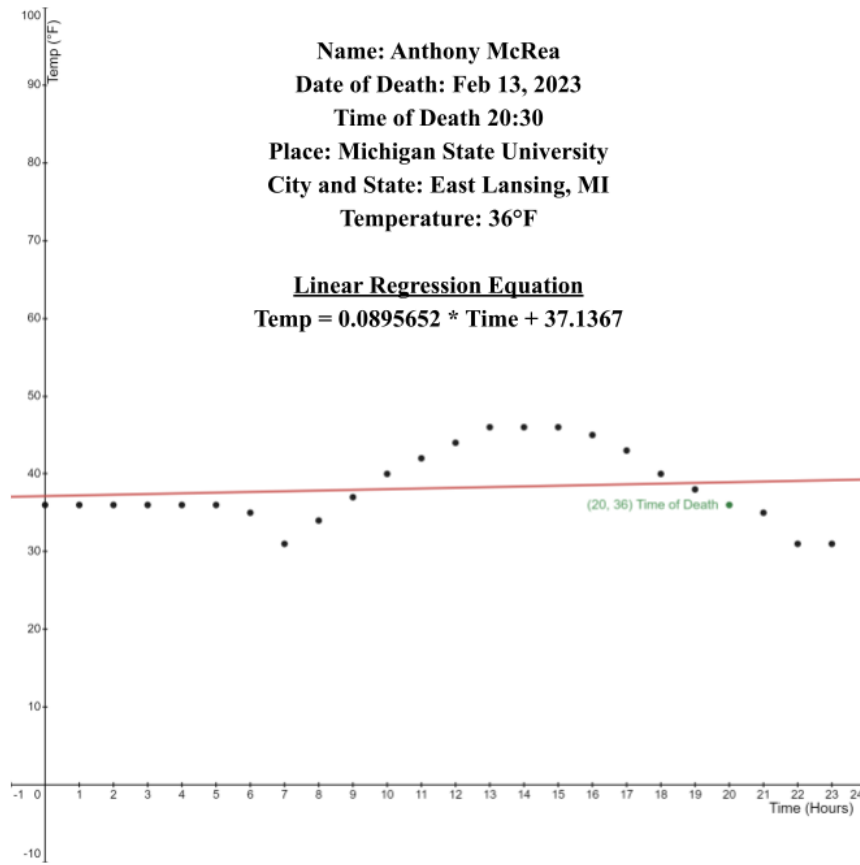

Each graph below shows how the temperature, humidity, and VPD changes throughout the day when each person passed away. Under each graph is a table that shows the temperature, humidity, and VPD at every hour during the day of the suicide. The average, standard deviation, and z-scores are also shown in every table. The average of the temperature, humidity, and VPD is calculated by taking the sum of the temperatures/humidities/VPDs and dividing the sum by 24 since there are 24 hours in one day. The standard deviation is calculated by the following steps:

1. For each temperature/humidity/VPD, subtract the mean from it and square the difference.
2. Find the average of the square differences.
3. Take the positive square root of the result found in the second step.

The z-scores show how far each of the temperatures/humidities/VPDs in terms of the number of standard deviations. The z-score is calculated by subtracting the average temperature/humidity/VPD from the actual temperature/humidity/VPD and dividing the difference by the standard deviation. If the magnitude of the z-score during the time of the suicide is greater than 1, then there might be some correlation between suicide and temperature/humidity/VPD.

On average, the temperature was increasing during the day when Anthony McRea committed suicide. The average temperature during the day was about 38.2°F, and the temperature during the time of the suicide was 36°F, which was not much lower than the average temperature during the day. The z-score was about -0.46, which is less than 1 in magnitude. Based on this, there is no correlation between temperature and suicide.

On average, the humidity was increasing during the day when Anthony McRea committed suicide. The average humidity during the day was about 61.7%, and the humidity during the time of the suicide was 73%, which was higher than the average humidity during the day. The z-score during the time of suicide was about 1.16, which is greater than 1 in magnitude. Also, starting from 19:53, the humidity increases. Based on this, there is some correlation between the increase in humidity and suicide.

On average, the VPD was decreasing during the day when Anthony McRea committed suicide. The average VPD during the day was about 0.31 kPa, and the VPD during the time of the suicide was about 0.19 kPa, which was much lower than the average VPD during the day. The z-score was about -1.01, which is greater than 1 in magnitude. Also, starting from 15:53, the VPD started to decrease. Based on this, there is some correlation between the decrease in VPD and suicide.

On average, the humidity was decreasing during the day when Sam Westmoreland committed suicide. The average humidity during the day was about 52.1%, and the humidity during the time of the suicide was somewhere between 50% and 88%, which was on average higher than the average humidity during the day. Even though it is uncertain what exact time Westmoreland passed away, the humidity was high most of the time in the time range when he passed away. Even the z-scores were greater than 1 in magnitude most of the time in the time range.

On average, the temperature was increasing during the day when Thomas H. Lee committed suicide. The average temperature during the day was about 39.5°F, and the temperature during the time of the suicide was 38°F, which was not much smaller than the average temperature during the day. The z-score was about -0.92, which is less than 1 in magnitude. Based on this, there is no correlation between temperature and suicide.

On average, the VPD was increasing during the day when Thomas H. Lee committed suicide. The average VPD during the day was about 0.16 kPa, and the VPD during the time of the suicide was about 0.09 kPa, which was lower than the average VPD during the day. The z-score was about -0.64, which is less than 1 in magnitude. However, since the VPD during the time of suicide was less than 0.15, there is some correlation between VPD and suicide.

Based on the sample of six people who died either from homicide or suicide, there is no correlation between temperature and death; however there is some correlation between humidity, VPD, and death. Five of the people from the sample have died when the humidity was high or started to increase and the VPD was low or started to decrease. From the data, there is evidence that there is global warming and that there is a connection between global warming and death whether it is was homicide or suicide.
